

Array Calculator

Your task is to implement the method, which calculates a product of N integers in array.

Example:

If we have an array: [1,2,3,4,5,6,7,8,9,0] and N = 3, the result of the function should be equal 504 (7 * 8 * 9).

If we have an array: [-1, 2, -3, 4, -5, 6, -7] and N = 5, the result should be equal to 1680 (2 * 4 * -5 * 6 * -7).

- Positive, negative and zero integers are calculated.
- Non-integer values (string, etc.) should not be included in calculation.
- If N is higher than number of integers in array, include all available integers.
